

5

ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER

FIELD OF THE INVENTION

This invention relates to electro-kinetic conversion of electrical energy into fluid flow of an ionizable dielectric medium, and more specifically to methods and devices
10 for electro-kinetically producing a flow of air from which particulate matter has been substantially removed. Preferably the air flow should contain safe amounts of ozone (O_3).

15

BACKGROUND OF THE INVENTION

The use of an electric motor to rotate a fan blade to create an air flow has long been known in the art. Unfortunately, such fans produce substantial noise, and can present a hazard to children who may be tempted to poke a
20 finger or a pencil into the moving fan blade. Although such fans can produce substantial air flow, e.g., 1,000 ft^3 /minute or more, substantial electrical power is required to operate the motor, and essentially no conditioning of the flowing air occurs.

25

It is known to provide such fans with a HEPA-compliant filter element to remove particulate matter larger than perhaps 0.3 μm . Unfortunately, the resistance to air flow presented by the filter element may require doubling
30 the electric motor size to maintain a desired level of airflow. Further, HEPA-compliant filter elements are expensive, and can represent a substantial portion of the sale price of a HEPA-compliant filter-fan unit. While such filter-fan units can condition the air by removing
35 large particles, particulate matter small enough to pass

through the filter element is not removed, including bacteria, for example.

5 It is also known in the art to produce an air flow using electro-kinetic techniques, by which electrical power is directly converted into a flow of air without mechanically moving components. One such system is described in U.S. patent no. 4,789,801 to Lee (1988), depicted herein in simplified form as Figures 1A and 1B. Lee's system 10 includes an array of small area ("minisectional") electrodes 20 that is spaced-apart symmetrically from an array of larger area ("maxisectional") electrodes 30. The positive terminal of a pulse generator 40 that outputs a train of high voltage pulses (e.g., 0 to perhaps + 15 5 KV) is coupled to the minisectional array, and the negative pulse generator terminal is coupled to the maxisectional array.

20 The high voltage pulses ionize the air between the arrays, and an air flow 50 from the minisectional array toward the maxisectional array results, without requiring any moving parts. Particulate matter 60 in the air is entrained within the airflow 50 and also moves towards the maxisectional electrodes 30. Much of the particulate 25 matter is electrostatically attracted to the surface of the maxisectional electrode array, where it remains, thus conditioning the flow of air exiting system 10. Further, the high voltage field present between the electrode arrays can release ozone into the ambient environment, 30 which appears to destroy or at least alter whatever is entrained in the airflow, including for example, bacteria.

35 In the embodiment of Figure 1A, minisectional electrodes 20 are circular in cross-section, having a diameter of about 0.003" (0.08 mm), whereas the maxisectional electrodes 30 are substantially larger in area and define a

"teardrop" shape in cross-section. The ratio of cross-sectional areas between the maxisectional and minisectional electrodes is not explicitly stated, but from Lee's figures appears to exceed 10:1. As shown in Figure 1A herein, the bulbous front surfaces of the maxisectional electrodes face the minisectional electrodes, and the somewhat sharp trailing edges face the exit direction of the air flow. The "sharpened" trailing edges on the maxisectional electrodes apparently promote good electrostatic attachment of particular matter entrained in the airflow. Lee does not disclose how the teardrop shaped maxisectional electrodes are fabricated, but presumably they are produced using a relatively expensive mold-casting or an extrusion process.

In another embodiment shown herein as Figure 1B, Lee's maxisectional sectional electrodes 30 are symmetrical and elongated in cross-section. The elongated trailing edges on the maxisectional electrodes provide increased area upon which particulate matter entrained in the airflow can attach. Lee states that precipitation efficiency and desired reduction of anion release into the environment can result from including a passive third array of electrodes 70. Understandably, increasing efficiency by adding a third array of electrodes will contribute to the cost of manufacturing and maintaining the resultant system.

While the electrostatic techniques disclosed by Lee are advantageous to conventional electric fan-filter units, Lee's maxisectional electrodes are relatively expensive to fabricate. Further, increased filter efficiency beyond what Lee's embodiments can produce would be advantageous, especially without including a third array of electrodes.

Thus, there is a need for an electro-kinetic air transporter-conditioner that provides improved efficiency over Lee-type systems, without requiring expensive production techniques to fabricate the electrodes. Preferably such a conditioner should function efficiently without requiring a third array of electrodes. Further, such a conditioner should permit user-selection of safe amounts of ozone to be generated, for example to remove odor from the ambient environment.

The present invention provides a method and apparatus for electro-kinetically transporting and conditioning air.

SUMMARY OF THE PRESENT INVENTION

The present invention provides an electro-kinetic system for transporting and conditioning air without moving parts. The air is conditioned in the sense that it is ionized and contains safe amounts of ozone.

Applicants' electro-kinetic air transporter-conditioner includes a louvered or grilled body that houses an ionizer unit. The ionizer unit includes a high voltage DC inverter that boosts common 110 VAC to high voltage, and a generator that receives the high voltage DC and outputs high voltage pulses of perhaps 10 KV peak-to-peak, although an essentially 100% duty cycle (e.g., high voltage DC) output could be used instead of pulses. The unit also includes an electrode assembly unit comprising first and second spaced-apart arrays of conducting electrodes, the first array and second array being coupled, respectively, preferably to the positive and negative output ports of the high voltage generator.

The electrode assembly preferably is formed using first and second arrays of readily manufacturable electrode types. In one embodiment, the first array comprises wire-like electrodes and the second array comprises "U"-

shaped electrodes having one or two trailing surfaces. In an even more efficient embodiment, the first array includes at least one pin or cone-like electrode and the second array is an annular washer-like electrode. The electrode assembly may comprise various combinations of the described first and second array electrodes. In the various embodiments, the ratio between effective area of the second array electrodes to the first array electrodes is at least about 20:1.

The high voltage pulses create an electric field between the first and second electrode arrays. This field produces an electro-kinetic airflow going from the first array toward the second array, the airflow being rich in preferably a net surplus of negative ions and in ozone. Ambient air including dust particles and other undesired components (germs, perhaps) enter the housing through the grill or louver openings, and ionized clean air (with ozone) exits through openings on the downstream side of the housing.

The dust and other particulate matter attaches electrostatically to the second array (or collector) electrodes, and the output air is substantially clean of such particulate matter. Further, ozone generated by the present invention can kill certain types of germs and the like, and also eliminates odors in the output air. Preferably the transporter operates in periodic bursts, and a control permits the user to temporarily increase the high voltage pulse generator output, e.g., to more rapidly eliminate odors in the environment.

Other features and advantages of the invention will appear from the following description in which the preferred embodiments have been set forth in detail, in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a plan, cross-sectional view, of a first embodiment of a prior art electro-kinetic air transporter-conditioner system, according to the prior art;

20

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Figs. 2A and 2B depict an electro-kinetic air transporter-conditioner system 100 whose housing 102 includes preferably rear-located intake vents or louvers 104 and preferably front and side-located exhaust vents 106, and a base pedestal 108. Internal to the transporter housing is an ion generating unit 160, preferably powered by an AC:DC power supply that is energizable using switch S1. Ion generating unit 160 is self-contained in that other than ambient air, nothing is required from beyond the transporter housing, save external operating potential, for operation of the present invention.

35 The upper surface of housing 102 includes a user-liftable handle 112 to which is affixed an electrode assembly 220 that comprises a first array 230 of electrodes 232 and a second array 240 of electrodes 242. The first and second

arrays of electrodes are coupled in series between the output terminals of ion generating unit 160, as best seen in Fig. 3. The ability to lift handle 112 provides ready access to the electrodes comprising the electrode assembly, for purposes of cleaning and, if necessary, replacement.

The general shape of the invention shown in Figs. 2A and 2B is not critical. The top-to-bottom height of the preferred embodiment is perhaps 1 m, with a left-to-right width of perhaps 15 cm, and a front-to-back depth of perhaps 10 cm, although other dimensions and shapes may of course be used. A louvered construction provides ample inlet and outlet venting in an economical housing configuration. There need be no real distinction between vents 104 and 106, except their location relative to the second array electrodes, and indeed a common vent could be used. These vents serve to ensure that an adequate flow of ambient air may be drawn into or made available to the present invention, and that an adequate flow of ionized air that includes safe amounts of O_3 flows out from unit 130.

As will be described, when unit 100 is energized with S1, high voltage output by ion generator 160 produces ions at the first electrode array, which ions are attracted to the second electrode array. The movement of the ions in an "IN" to "OUT" direction carries with them air molecules, thus electrokinetically producing an outflow of ionized air. The "IN" notion in Figs. 2A and 2B denote the intake of ambient air with particulate matter 60. The "OUT" notation in the figures denotes the outflow of cleaned air substantially devoid of the particulate matter, which adheres electrostatically to the surface of the second array electrodes. In the process of generating the ionized air flow, safe amounts of ozone (O_3) are beneficially produced. It may be

desired to provide the inner surface of housing 102 with an electrostatic shield to reduces detectable electromagnetic radiation. For example, a metal shield could be disposed within the housing, or portions of the interior of the housing could be coated with a metallic paint to reduce such radiation.

As best seen in Fig. 3, ion generating unit 160 includes a high voltage generator unit 170 and circuitry 180 for converting raw alternating voltage (e.g., 117 VAC) into direct current ("DC") voltage. Circuitry 180 preferably includes circuitry controlling the shape and/or duty cycle of the generator unit output voltage (which control is altered with user switch S2). Circuitry 180 preferably also includes a pulse mode component, coupled to switch S3, to temporarily provide a burst of increased output ozone. Circuitry 180 can also include a timer circuit and a visual indicator such as a light emitting diode ("LED"). The LED or other indicator (including, if desired, audible indicator) signals when ion generation is occurring. The timer can automatically halt generation of ions and/or ozone after some predetermined time, e.g., 30 minutes. indicator(s), and/or audible indicator(s).

As shown in Fig. 3, high voltage generator unit 170 preferably comprises a low voltage oscillator circuit 190 of perhaps 20 KHz frequency, that outputs low voltage pulses to an electronic switch 200, e.g., a thyristor or the like. Switch 200 switchably couples the low voltage pulses to the input winding of a step-up transformer T1. The secondary winding of T1 is coupled to a high voltage multiplier circuit 210 that outputs high voltage pulses. Preferably the circuitry and components comprising high voltage pulse generator 170 and circuit 180 are fabricated on a printed circuit board that is mounted within housing 102. If desired, external audio input

(e.g., from a stereo tuner) could be suitably coupled to oscillator 190 to acoustically modulate the kinetic airflow produced by unit 160. The result would be an electrostatic loudspeaker, whose output air flow is audible to the human ear in accordance with the audio input signal. Further, the output air stream would still include ions and ozone.

Output pulses from high voltage generator 170 preferably are at least 10 KV peak-to-peak with an effective DC offset of perhaps half the peak-to-peak voltage, and have a frequency of perhaps 20 KHz. The pulse train output preferably has a duty cycle of perhaps 10%, which will promote battery lifetime. Of course, different peak-peak amplitudes, DC offsets, pulse train waveshapes, duty cycle, and/or repetition frequencies may instead be used. Indeed, a 100% pulse train (e.g., an essentially DC high voltage) may be used, albeit with shorter battery lifetime. Thus, generator unit 170 may (but need not) be referred to as a high voltage pulse generator.

Frequency of oscillation is not especially critical but frequency of at least about 20 KHz is preferred as being inaudible to humans. If pets will be in the same room as the present invention, it may be desired to utilize an even higher operating frequency, to prevent pet discomfort and/or howling by the pet.

The output from high voltage pulse generator unit 170 is coupled to an electrode assembly 220 that comprises a first electrode array 230 and a second electrode array 240. Unit 170 functions as a DC:DC high voltage generator, and could be implemented using other circuitry and/or techniques to output high voltage pulses that are input to electrode assembly 220.

In the embodiment of Fig. 3, the positive output terminal of unit 170 is coupled to first electrode array 230, and the negative output terminal is coupled to second electrode array 240. This coupling polarity has been found to work well, including minimizing unwanted audible electrode vibration or hum. An electrostatic flow of air is created, going from the first electrode array towards the second electrode array. (This flow is denoted "OUT" in the figures.) Accordingly electrode assembly 220 is mounted within transporter system 100 such that second electrode array 240 is closer to the OUT vents and first electrode array 230 is closer to the IN vents.

When voltage or pulses from high voltage pulse generator 170 are coupled across first and second electrode arrays 230 and 240, it is believed that a plasma-like field is created surrounding electrodes 232 in first array 230. This electric field ionizes the ambient air between the first and second electrode arrays and establishes an "OUT" airflow that moves towards the second array. It is understood that the IN flow enters via vent(s) 104, and that the OUT flow exits via vent(s) 106.

It is believed that ozone and ions are generated simultaneously by the first array electrode(s) 232, essentially as a function of the potential from generator 170 coupled to the first array. Ozone generation may be increased or decreased by increasing or decreasing the potential at the first array. Coupling an opposite polarity potential to the second array electrode(s) 242 essentially accelerates the motion of ions generated at the first array, producing the air flow denoted as "OUT" in the figures. As the ions move toward the second array, it is believed that they push or move air molecules toward the second array. The relative velocity of this motion may be increased by decreasing the potential at the second array relative to the potential at the first array.

For example, if +10 KV were applied to the first array electrode(s), and no potential were applied to the second array electrode(s), a cloud of ions (whose net charge is positive) would form adjacent the first electrode array.

5 Further, the relatively high 10 KV potential would generate substantial ozone. By coupling a relatively negative potential to the second array electrode(s), the velocity of the air mass moved by the net emitted ions increases, as momentum of the moving ions is conserved.

10

On the other hand, if it were desired to maintain the same effective outflow (OUT) velocity but to generate less ozone, the exemplary 10 KV potential could be divided between the electrode arrays. For example, generator
15 170 could provide +4 KV (or some other fraction) to the first array electrode(s) and -6 KV (or some other fraction) to the second array electrode(s). In this example, it is understood that the +4 KV and the -6 KV are measured relative to ground. Understandably it is desired
20 that the present invention operate to output safe amounts of ozone. Accordingly, the high voltage is preferably fractionalized with about +4 KV applied to the first array electrode(s) and about -6 KV applied to the second array electrodes.

25

As noted, outflow (OUT) preferably includes safe amounts of O_3 that can destroy or at least substantially alter bacteria, germs, and other living (or quasi-living) matter subjected to the outflow. Thus, when switch S1 is
30 closed and B1 has sufficient operating potential, pulses from high voltage pulse generator unit 170 create an outflow (OUT) of ionized air and O_3 . When S1 is closed, LED will visually signal when ionization is occurring.

35 Preferably operating parameters of the present invention are set during manufacture and are not user-adjustable. For example, increasing the peak-to-peak output voltage

and/or duty cycle in the high voltage pulses generated by unit 170 can increase air flowrate, ion content, and ozone content. In the preferred embodiment, output flow-rate is about 200 feet/minute, ion content is about
5 2,000,000/cc and ozone content is about 40 ppb (over ambient) to perhaps 2,000 ppb (over ambient). Decreasing the R2/R1 ratio below about 20:1 will decrease flow rate, as will decreasing the peak-to-peak voltage and/or duty cycle of the high voltage pulses coupled between the
10 first and second electrode arrays.

In practice, unit 100 is placed in a room and connected to an appropriate source of operating potential, typically 117 VAC. With S1 energized, ionization unit
15 160 emits ionized air and preferably some ozone (O_3) via outlet vents 150. The air flow, coupled with the ions and ozone freshens the air in the room, and the ozone can beneficially destroy or at least diminish the undesired effects of certain odors, bacteria, germs, and the like.
20 The air flow is indeed electro-kinetically produced, in that there are no intentionally moving parts within the present invention. (As noted, some mechanical vibration may occur within the electrodes.) As will be described with respect to Fig. 4A, it is desirable that the present
25 invention actually output a net surplus of negative ions, as these ions are deemed more beneficial to health than are positive ions.

Having described various aspects of the invention in
30 general, preferred embodiments of electrode assembly 220 will now be described. In the various embodiments, electrode assembly 220 will comprise a first array 230 of at least one electrode 232, and will further comprise a second array 240 of preferably at least one electrode
35 242. Understandably material(s) for electrodes 232 and 242 should conduct electricity, be resilient to corrosive

effects from the application of high voltage, yet be strong enough to be cleaned.

5 In the various electrode assemblies to be described herein, electrode(s) 232 in the first electrode array 230 are preferably fabricated from tungsten. Tungsten is sufficiently robust to withstand cleaning, has a high melting point to retard breakdown due to ionization, and has a rough exterior surface that seems to promote
10 efficient ionization. On the other hand, electrodes 242 preferably will have a highly polished exterior surface to minimize unwanted point-to-point radiation. As such, electrodes 242 preferably are fabricated from stainless steel, brass, among other materials. The polished
15 surface of electrodes 232 also promotes ease of electrode cleaning.

In contrast to the prior art electrodes disclosed by Lee, electrodes 232 and 242 according to the present invention
20 are light weight, easy to fabricate, and lend themselves to mass production. Further, electrodes 232 and 242 described herein promote more efficient generation of ionized air, and production of safe amounts of ozone, O_3 .

25 In the present invention, a high voltage pulse generator 170 is coupled between the first electrode array 230 and the second electrode array 240. The high voltage pulses produce a flow of ionized air that travels in the direction from the first array towards the second array
30 (indicated herein by hollow arrows denoted "OUT"). As such, electrode(s) 232 may be referred to as an emitting electrode, and electrodes 242 may be referred to as collector electrodes. This outflow advantageously contains safe amounts of O_3 , and exits the present
35 invention from vent(s) 106.

According to the present invention, it is preferred that the positive output terminal or port of the high voltage pulse generator be coupled to electrodes 232, and that the negative output terminal or port be coupled to electrodes 242. It is believed that the net polarity of the emitted ions is positive, e.g., more positive ions than negative ions are emitted. In any event, the preferred electrode assembly electrical coupling minimizes audible hum from electrodes 232 contrasted with reverse polarity (e.g., interchanging the positive and negative output port connections).

However, while generation of positive ions is conducive to a relatively silent air flow, from a health standpoint, it is desired that the output air flow be richer in negative ions, not positive ions. It is noted that in some embodiments, however, one port (preferably the negative port) of the high voltage pulse generator may in fact be the ambient air. Thus, electrodes in the second array need not be connected to the high voltage pulse generator using wire. Nonetheless, there will be an "effective connection" between the second array electrodes and one output port of the high voltage pulse generator, in this instance, via ambient air.

Turning now to the embodiments of Figs. 4A and 4B, electrode assembly 220 comprises a first array 230 of wire electrodes 232, and a second array 240 of generally "U"-shaped electrodes 242. In preferred embodiments, the number N1 of electrodes comprising the first array will preferably differ by one relative to the number N2 of electrodes comprising the second array. In many of the embodiments shown, $N2 > N1$. However, if desired, in Fig. 4A, additional first electrodes 232 could be added at the out ends of array 230 such that $N1 > N2$, e.g., five electrodes 232 compared to four electrodes 242.

Electrodes 232 are preferably lengths of tungsten wire, whereas electrodes 242 are formed from sheet metal, preferably stainless steel, although brass or other sheet metal could be used. The sheet metal is readily formed to define side regions 244 and bulbous nose region 246 for hollow elongated "U" shaped electrodes 242. While Fig. 4A depicts four electrodes 242 in second array 240 and three electrodes 232 in first array 230, as noted, other numbers of electrodes in each array could be used, preferably retaining a symmetrically staggered configuration as shown. It is seen in Fig. 4A that while particulate matter 60 is present in the incoming (IN) air, the outflow (OUT) air is substantially devoid of particulate matter, which adheres to the preferably large surface area provided by the second array electrodes (see Fig. 4B).

As best seen in Fig. 4B, the spaced-apart configuration between the arrays is staggered such that each first array electrode 232 is substantially equidistant from two second array electrodes 242. This symmetrical staggering has been found to be an especially efficient electrode placement. Preferably the staggering geometry is symmetrical in that adjacent electrodes 232 or adjacent electrodes 242 are spaced-apart a constant distance, Y1 and Y2 respectively. However, a non-symmetrical configuration could also be used, although ion emission and air flow would likely be diminished. Also, it is understood that the number of electrodes 232 and 242 may differ from what is shown.

In Figs. 4A, typically dimensions are as follows: diameter of electrodes 232 is about 0.08 mm, distances Y1 and Y2 are each about 16 mm, distance X1 is about 16 mm, distance L is about 20 mm, and electrode heights Z1 and Z2 are each about 1 m. The width W of electrodes 242 is preferably about 4 mm, and the thickness of the material

from which electrodes 242 are formed is about 0.5 mm. Of course other dimensions and shapes could be used. It is preferred that electrodes 232 be small in diameter to help establish a desired high voltage field. On the other hand, it is desired that electrodes 232 (as well as electrodes 242) be sufficiently robust to withstand occasional cleaning.

Electrodes 232 in first array 230 are coupled by a conductor 234 to a first (preferably positive) output port of high voltage pulse generator 170, and electrodes 242 in second array 240 are coupled by a conductor 244 to a second (preferably negative) output port of generator 170. It is relatively unimportant where on the various electrodes electrical connection is made to conductors 234 or 244. Thus, by way of example Fig. 4B depicts conductor 244 making connection with some electrodes 242 internal to bulbous end 246, while other electrodes 242 make electrical connection to conductor 244 elsewhere on the electrode. Electrical connection to the various electrodes 242 could also be made on the electrode external surface providing no substantial impairment of the outflow airstream results.

To facilitate removing the electrode assembly from unit 100 (as shown in Fig. 2B), it is preferred that the lower end of the various electrodes fit against mating portions of wire or other conductors 234 or 244. For example, "cup-like" members can be affixed to wires 234 and 244 into which the free ends of the various electrodes fit when electrode array 220 is inserted completely into housing 102 of unit 100.

The ratio of the effective electric field emanating area of electrode 232 to the nearest effective area of electrodes 242 is at least about 15:1, and preferably is

at least 20:1. Thus, in the embodiment of Fig. 4A and Fig. 4B, the ratio $R2/R1 \approx 2 \text{ mm}/0.04 \text{ mm} \approx 50:1$.

5 In this and the other embodiments to be described herein, ionization appears to occur at the smaller electrode(s) 232 in the first electrode array 230, with ozone production occurring as a function of high voltage arcing. For example, increasing the peak-to-peak voltage amplitude and/or duty cycle of the pulses from the high
10 voltage pulse generator 170 can increase ozone content in the output flow of ionized air. If desired, user-control S2 can be used to somewhat vary ozone content by varying (in a safe manner) amplitude and/or duty cycle. Specific circuitry for achieving such control is known in the art
15 and need not be described in detail herein.

Note the inclusion in Figs. 4A and 4B of at least one output controlling electrode 243, preferably electrically coupled to the same potential as the second array
20 electrodes. Electrode 243 preferably defines a pointed shape in side profile, e.g., a triangle. The sharp point on electrode(s) 243 causes generation of substantial negative ions (since the electrode is coupled to relatively negative high potential). These negative ions
25 neutralize excess positive ions otherwise present in the output air flow, such that the OUT flow has a net negative charge. Electrode(s) 243 preferably are stainless steel, copper, or other conductor, and are perhaps 20 mm high and about 12 mm wide at the base.

30 Another advantage of including pointed electrodes 243 is that they may be stationarily mounted within the housing of unit 100, and thus are not readily reached by human hands when cleaning the unit. Were it otherwise, the
35 sharp point on electrode(s) 243 could easily cause cuts. The inclusion of one electrode 243 has been found sufficient to provide a sufficient number of output

negative ions, but more such electrodes may be included.

In the embodiment of Figs. 4A and 4C, each "U"-shaped electrode 242 has two trailing edges that promote efficient kinetic transport of the outflow of ionized air and O₃. Note the inclusion on at least one portion of a trailing edge of a pointed electrode region 243'. Electrode region 243' helps promote output of negative ions, in the same fashion as was described with respect to Figs. 4A and 4B. Note, however, the higher likelihood of a user cutting himself or herself when wiping electrodes 242 with a cloth or the like to remove particulate matter deposited thereon. In Fig. 4C and the figures to follow, the particulate matter is omitted for ease of illustration. However, from what was shown in Figs. 2A-4B, particulate matter will be present in the incoming air, and will be substantially absent from the outgoing air. As has been described, particulate matter 60 typically will be electrostatically precipitated upon the surface area of electrodes 242.

Note that the embodiments of Figs. 4C and 4D depict somewhat truncated versions of electrodes 242. Whereas dimension L in the embodiment of Figs. 4A and 4B was about 20 mm, in Figs. 4C and 4D, L has been shortened to about 8 mm. Other dimensions in Fig. 4C preferably are similar to those stated for Figs. 4A and 4B. In Figs. 4C and 4D, the inclusion of point-like regions 246 on the trailing edge of electrodes 242 seems to promote more efficient generation of ionized air flow. It will be appreciated that the configuration of second electrode array 240 in Fig. 4C can be more robust than the configuration of Figs. 4A and 4B, by virtue of the shorter trailing edge geometry. As noted earlier, a symmetrical staggered geometry for the first and second electrode arrays is preferred for the configuration of Fig. 4C.

In the embodiment of Fig. 4D, the outermost second electrodes, denoted 242-1 and 242-2, have substantially no outermost trailing edges. Dimension L in Fig. 4D is preferably about 3 mm, and other dimensions may be as stated for the configuration of Figs. 4A and 4B. Again, the R2/R1 ratio for the embodiment of Fig. 4D preferably exceeds about 20:1.

Figs. 4E and 4F depict another embodiment of electrode assembly 220, in which the first electrode array comprises a single wire electrode 232, and the second electrode array comprises a single pair of curved "L"-shaped electrodes 242, in cross-section. Typical dimensions, where different than what has been stated for earlier-described embodiments, are $X1 \approx 12$ mm, $Y1 \approx 6$ mm, $Y2 \approx 5$ mm, and $L1 \approx 3$ mm. The effective R2/R1 ratio is again greater than about 20:1. The fewer electrodes comprising assembly 220 in Figs. 4E and 4F promote economy of construction, and ease of cleaning, although more than one electrode 232, and more than two electrodes 242 could of course be employed. This embodiment again incorporates the staggered symmetry described earlier, in which electrode 232 is equidistant from two electrodes 242.

Fig. 4G and 4H shown yet another embodiment for electrode assembly 220. In this embodiment, first electrode array 230 is a length of wire 232, while the second electrode array 240 comprises a pair of rod or columnar electrodes 242. As in embodiments described earlier herein, it is preferred that electrode 232 be symmetrically equidistant from electrodes 242. Wire electrode 232 is preferably perhaps 0.08 mm tungsten, whereas columnar electrodes 242 are perhaps 2 mm diameter stainless steel. Thus, in this embodiment the R2/R1 ratio is about 25:1. Other dimensions may be similar to other configurations, e.g., Fig. 4E, 4F. Of course electrode assembly 220 may

comprise more than one electrode 232, and more than two electrodes 242.

5 An especially preferred embodiment is shown in Fig. 4I and Fig. 4J. In these figures, the first electrode assembly comprises a single pin-like element 232 disposed coaxially with a second electrode array that comprises a single ring-like electrode 242 having a rounded inner opening 246. However, as indicated by phantom elements 10 232', 242', electrode assembly 220 may comprise a plurality of such pin-like and ring-like elements. Preferably electrode 232 is tungsten, and electrode 242 is stainless steel.

15 Typical dimensions for the embodiment of Fig. 4I and Fig. 4J are $L1 \approx 10$ mm, $X1 \approx 9.5$ mm, $T \approx 0.5$ mm, and the diameter of opening 246 is about 12 mm. Dimension $L1$ preferably is sufficiently long that upstream portions of electrode 232 (e.g., portions to the left in Fig. 4I) do 20 not interfere with the electrical field between electrode 232 and the collector electrode 242. However, as shown in Fig. 4J, the effect $R2/R1$ ratio is governed by the tip geometry of electrode 232. Again, in the preferred embodiment, this ratio exceeds about 20:1. Lines drawn 25 in phantom in Fig. 4J depict theoretical electric force field lines, emanating from emitter electrode 232, and terminating on the curved surface of collector electrode 246. Preferably the bulk of the field emanates within about $\pm 45^\circ$ of coaxial axis between electrode 232 and 30 electrode 242. On the other hand, if the opening in electrode 242 and/or electrode 232 and 242 geometry is such that too narrow an angle about the coaxial axis exists, air flow will be unduly restricted.

35 One advantage of the ring-pin electrode assembly configuration shown in Fig. 4I is that the flat regions of ring-like electrode 242 provide sufficient surface

area to which particulate matter 60 entrained in the moving air stream can attach, yet be readily cleaned.

Further, the ring-pin configuration advantageously
5 generates more ozone than prior art configurations, or the configurations of Figs. 4A-4H. For example, whereas the configurations of Figs. 4A-4H may generate perhaps 50 ppb ozone, the configuration of Fig. 4I can generate about 2,000 ppb ozone.

10

Nonetheless it will be appreciated that applicants' first array pin electrodes may be utilized with the second array electrodes of Figs. 4A-4H. Further, applicants' second array ring electrodes may be utilized with the
15 first array electrodes of Figs. 4A-4H. For example, in modifications of the embodiments of Figs. 4A-4H, each wire or columnar electrode 232 is replaced by a column of electrically series-connected pin electrodes (e.g., as shown in Figs. 4I-4K), while retaining the second
20 electrode arrays as depicted in these figures. By the same token, in other modifications of the embodiments of Figs. 4A-4H, the first array electrodes can remain as depicted, but each of the second array electrodes 242 is replaced by a column of electrically series-connected
25 ring electrodes (e.g., as shown in Figs. 4I-4K).

In Fig. 4J, a detailed cross-sectional view of the central portion of electrode 242 in Fig. 4I is shown. As best seen in Fig. 4J, curved region 246 adjacent the
30 central opening in electrode 242 appears to provide an acceptably large surface area to which many ionization paths from the distal tip of electrode 232 have substantially equal path length. Thus, while the distal tip (or emitting tip) of electrode 232 is advantageously
35 small to concentrate the electric field between the electrode arrays, the adjacent regions of electrode 242 preferably provide many equidistant inter-electrode array

paths. A high exit flowrate of perhaps 90 feet/minute and 2,000 ppb range ozone emission attainable with this configuration confirm a high operating efficiency.

5 In Fig. 4K, one or more electrodes 232 is replaced by a
conductive block 232" of carbon fibers, the block having
a distal surface in which projecting fibers 233-1, ...
233-N take on the appearance of a "bed of nails". The
projecting fibers can each act as an emitting electrode
10 and provide a plurality of emitting surfaces. Over a
period of time, some or all of the electrodes will
literally be consumed, whereupon graphite block 232" will
be replaced. Materials other than graphite may be used
for block 232" providing the material has a surface with
15 projecting conductive fibers such as 233-N.

As described, the net output of ions is influenced by
placing a bias element (e.g., element 243) near the
output stream and preferably near the downstream side of
20 the second array electrodes. If no ion output were
desired, such an element could achieve substantial
neutralization. It will also be appreciated that the
present invention could be adjusted to produce ions
without producing ozone, if desired.

25 Modifications and variations may be made to the disclosed
embodiments without departing from the subject and spirit
of the invention as defined by the following claims.

30

WHAT IS CLAIMED IS:

1. An electro-kinetic air transporter-conditioner, comprising:

- 5 a housing defining at least one vent; and
a self-contained ion generator, disposed within said housing;

said ion generator producing ionized air that flows electrostatically from said vent.

10 2. The transporter-conditioner of claim 1, wherein said ion generator includes:

a high voltage generator outputting a signal whose duty cycle may be varied from about 10% to about 100%;

15 an electrode assembly comprising a first electrode array effectively coupled to a first output port of said generator, and a second electrode array effectively coupled to a second output port of said generator, wherein one said output port may be at a same potential as ambient air;

20 wherein particulate matter in ambient air is electrostatically attracted to said second electrode array, and wherein said ion generator further creates ozone that flows electrostatically from said vent.

25 3. The transporter-conditioner of claim 2, wherein said high voltage generator has a characteristic selected from a group consisting of (a) said high voltage generator provides a first potential measurable relative to ground to said first electrode array and provides a
30 second potential measurable relative to ground to said second electrode array, and (b) said high voltage generator provides a first positive potential measurable relative to ground to said first electrode array and provides a second negative potential measurable relative
35 to ground to said second electrode array.

4. The transporter-conditioner of claim 2,
wherein:

5 said first electrode array includes at least one
electrode selected from a group consisting of (i) an
electrically conductive tapered pin-shaped electrode, and
(ii) a portion of conductive material having a end
defining a plurality of projecting conductive fibers; and

10 said second electrode array includes an electrically
conductive ring-shaped electrode defining a central
through opening, said second electrode disposed coaxial
with and in a downstream direction from an emitting end
of an electrode in said first electrode array.

15 5. The transporter-conditioner of claim 4, wherein
said first electrode array includes at least one said
pin-shaped electrode, and said second electrode array has
at least one characteristic selected from a group
consisting of (i) said ring-shaped electrode defines in
cross-section a tapered region terminating towards said
20 central through opening, (ii) said ring-shaped electrode
defines in cross-section a rounded region terminating
towards said central through opening, (c) said ring-
shaped electrode defines in cross-section a rounded
profile terminating in said through opening, (d) a ratio
25 of effective radius of said ring-shaped electrode to
effective radius of said pin-shaped electrode exceeds
about 15:1, (e) said pin-shaped electrode includes
tungsten, (f) said pin-shaped electrode includes
stainless steel, (g) said pin-shaped electrode includes
30 projecting fibers of carbon, and (h) said ring-shaped
electrode includes stainless steel.

5. The transporter-conditioner of claim 2, wherein:
said first electrode array includes at least one
35 metal wire electrode; and

said second electrode array includes at least two
electrically conductive electrodes that in cross-section

define a "U"-shape having a bulbous nose region and first and second trailing edge regions;

the "U"-shaped electrodes being disposed such that said bulbous nose regions facing said metal wire electrode and are equidistant therefrom.

6. The transporter-conditioner of claim 5, wherein an electrode in said second electrode array has at least one characteristic selected from a group consisting of (i) a portion of one trailing edge region is longer than a remaining trailing edge region on said electrode, (ii) said trailing edge region defines at least one pointed projection facing downstream, and (iii) a ratio of effective radius of an electrode in said second electrode array to effective radius of said metal wire electrode exceeds about 15:1.

7. The transporter-conditioner of hair brush of claim 2, wherein:

said first electrode array includes at least one metal wire electrode; and

said second electrode array includes at least two electrically conductive electrodes that in cross-section define an "L"-shape having a curved nose region;

the "L"-shaped electrodes being disposed such that said curved nose regions face said metal wire electrode and are equidistant therefrom.

8. The transporter-conditioner of claim 2, wherein:

said first electrode array includes at least one metal wire electrode; and

said second electrode array includes at least two rod-like electrically conductive electrodes;

the rod-like electrodes being disposed such that said curved nose regions face said metal wire electrode and are equidistant therefrom.

9. The transporter-conditioner of claim 8, wherein a ratio of radius of one of said rod-like electrodes to radius of said wire electrode exceeds about 15:1.

5 10. The transporter-conditioner of claim 2, further including a bias electrode for determining net polarity of ions generated by said transporter-conditioner.

10 11. An electro-kinetic air transporter-conditioner, comprising:

a housing defining at least one vent; and

a self-contained ozone generator, disposed within said housing;

15 said ozone generator producing ozone that flows electrostatically from said vent to condition ambient air.

20 12. The electro-kinetic air transporter-conditioner of claim 11, wherein said ozone generator includes an ion generator comprising:

a high voltage generator outputting a signal whose duty cycle may be varied from about 10% to about 100%;

25 an electrode assembly comprising a first electrode array effectively coupled to a first output port of said generator, and a second electrode array effectively coupled to a second output port of said generator, wherein one said port may be at a same potential as ambient air;

30 said ion generator further creating ozone that flows electrostatically from said vent.

13. The electro-kinetic air transporter-conditioner of claim 12, wherein:

35 said first electrode array includes at least one electrode selected from a group consisting of (i) an electrically conductive tapered pin-shaped electrode, and

(ii) a portion of conductive material having a end defining a plurality of projecting conductive fibers; and said second electrode array includes an electrically conductive ring-shaped electrode defining a central through opening, said second electrode disposed coaxial with and in a downstream direction from an emitting end of an electrode in said first electrode array.

14. The electro-kinetic air transporter-conditioner of claim 13, wherein said first electrode array includes at least one said pin-shaped electrode, and said second electrode array has at least one characteristic selected from a group consisting of (i) said ring-shaped electrode defines in cross-section a tapered region terminating towards said central through opening, (ii) said ring-shaped electrode defines in cross-section a rounded region terminating towards said central through opening, (c) said ring-shaped electrode defines in cross-section a rounded profile terminating in said through opening, (d) a ratio of effective radius of said ring-shaped electrode to effective radius of said pin-shaped electrode exceeds about 15:1, (e) said pin-shaped electrode includes tungsten, (f) said pin-shaped electrode includes stainless steel, (g) said pin-shaped electrode includes projecting fibers of carbon, and (h) said ring-shaped electrode includes stainless steel.

15. The electro-kinetic air transporter-conditioner of claim 12, wherein:
said first electrode array includes at least one metal wire electrode; and
said second electrode array includes at least two electrically conductive electrodes that in cross-section define a "U"-shape having a bulbous nose region and first and second trailing edge regions;

the "U"-shaped electrodes being disposed such that said bulbous nose regions facing said metal wire electrode and are equidistant therefrom.

5 16. The electro-kinetic air transporter-conditioner
of claim 12, wherein an electrode in said second
electrode array has at least one characteristic selected
from a group consisting of (i) a portion of one trailing
edge region is longer than a remaining trailing edge
10 region on said electrode, (ii) said trailing edge region
defines at least one pointed projection facing
downstream, and (iii) a ratio of effective radius of an
electrode in said second electrode array to effective
radius of said metal wire electrode exceeds about 15:1.

15 17. The electro-kinetic air transporter-conditioner
of claim 12, wherein:

 said first electrode array includes at least one
metal wire electrode; and

20 said second electrode array includes at least two
electrically conductive electrodes that in cross-section
define an "L"-shape having a curved nose region;

 the "L"-shaped electrodes being disposed such that
said curved nose regions face said metal wire electrode
25 and are equidistant therefrom.

 18. The electro-kinetic air transporter-conditioner
of claim 12, wherein:

30 said first electrode array includes at least one
metal wire electrode; and

 said second electrode array includes at least two
rod-like electrically conductive electrodes;

 the rod-like electrodes being disposed such that
said curved nose regions face said metal wire electrode
35 and are equidistant therefrom.

19. The electro-kinetic air transporter-conditioner of claim 18, wherein a ratio of radius of one of said rod-like electrodes to radius of said wire electrode exceeds about 15:1.

5

20. A method of electro-kinetically providing a flow of cleaned air containing ions and ozone, the method comprising:

(a) providing a housing that includes an ion
10 generator having an electrode assembly comprising a first electrode array and a second electrode array; and

(b) disposing within said housing a high voltage generator having a first output port electrically coupled to said first electrode array, and having a second output
15 port electrically coupled to said second electrode array, wherein one said port may be at a potential of ambient air;

wherein at least some ambient air is ionized and electrostatically moved through said housing, said
20 ionized air including ozone.

21. The method of claim 21, wherein:

said first electrode array includes at least one metal wire electrode; and

25 said second electrode array includes at least two electrically conductive electrodes that in cross-section define a "U"-shape having a bulbous nose region and first and second trailing edge regions;

the "U"-shaped electrodes being disposed such that
30 said bulbous nose regions facing said metal wire electrode and are equidistant therefrom.

22. The method of claim 21, further including a bias electrode, coupled to said second electrode array so
35 as to control charge of ions output from said housing.

23. The method of claim 21, wherein:

said first electrode array includes an electrically
conductive tapered pin-shaped electrode;

5 said second electrode array includes an electrically
conductive ring-shaped electrode defining a central
through opening and being electrically coupled to a
second output port of said generator, said second
electrode being disposed coaxial with and in a downstream
direction from a tapered end of said tapered pin-shaped
electrode.

10

24. The method of claim 21, wherein:

said first electrode array includes at least one
metal wire electrode; and

15 said second electrode array includes at least two
electrically conductive rod-like electrodes; said rod-
like electrodes being equidistant from said metal wire
electrode.

20

25

30

35

ABSTRACT OF THE DISCLOSURE

An electro-kinetic electro-static air conditioner includes a self-contained ion generator that provides
5 electro-kinetically moved air with ions and safe amounts of ozone. The ion generator includes a high voltage pulse generator whose output pulses are coupled between first and second electrode arrays. Preferably the first array comprises one or more wire electrodes spaced
10 staggeringly apart from a second array comprising hollow "U"-shaped electrodes. Preferably a ratio between effective area of an electrode in the second array compared to effective area of an electrode in the first array exceeds about 15:1 and preferably is about 20:1.
15 An electric field produced by the high voltage pulses between the arrays produces an electrostatic flow of ionized air containing safe amounts of ozone. A bias electrode, electrically coupled to the second array electrodes, affects net polarity of ions generated. The
20 outflow of ionized air and ozone is thus conditioned.

PRELIMINARY AMENDMENT

Commissioner for Patents
Washington, D.C. 20231

Sir:

Prior to examination of the application, please amend the above-identified application as follows.

In the Specification:

On page 1, above the title: Field of the Invention, please add the following Claim of Priority and

Cross-References to Related Patent Applications:

Claim of Priority:

This application claims priority from provisional application entitled "FOCUS ELECTRODE, ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER DEVICES," Application No. 60/306,479, filed July 18, 2001 under 35 U.S.C. 119(e), which application is incorporated herein by reference. This application is a continuation of U.S. Patent Application No. 09/730,499 filed December 5, 2000, which is a continuation of U.S. Patent Application No. 09/186,471 filed November 5, 1998, now U.S. Patent No. 6,176,977, all of which are incorporated herein by reference.

Cross-Reference to Concurrently Filed Present Applications:

1. U.S. Patent Application No. 60/xxx,xxx, filed herewith, entitled "ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER DEVICES WITH AN UPSTREAM FOCUS ELECTRODE"; SHPR-01041US6
2. U.S. Patent Application No. 60/xxx,xxx, filed herewith, entitled "ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER DEVICES WITH TRAILING ELECTRODE"; SHPR-01041USE
3. U.S. Patent Application No. 60/xxx,xxx, filed herewith, entitled "ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER DEVICES WITH INTERSTITIAL ELECTRODE"; SHPR-01041USF
4. U.S. Patent Application No. 60/xxx,xxx, filed herewith, entitled "ELECTRO-KINETIC AIR TRANSPORTER-CONDITIONER DEVICES WITH ENHANCED COLLECTOR ELECTRODE"; SHPR-01041USG

25. An electro-kinetic air transporter-conditioner system comprising:

an upstanding, elongated housing having a back air inlet vent, right and left side outlet vents and a front outlet vent; and

an ion generating unit positioned in said housing, said ion generating unit causing air to flow from the back air inlet vent to the right and left side outlet vents and to the front outlet vent.

26. The system of claim 25 wherein said ion generating unit includes a first ion emitter electrode and a second particle collector electrode.

27. The system of claim 25 wherein said ion generating unit includes a first ion emitter electrode that is located adjacent to the back air inlet vent and a second particle collector electrode that is located adjacent the right and left side outlet vents and the front outlet vent.

28. The system of claim 25 wherein said housing has elongated recesses.

29. The system of claim 25 wherein said ion generating unit includes a first ion emitter electrode and a second collector electrode array, wherein said second collector electrode array has a plurality of elongated fins extending along the elongated housing.

30. The system of claim 25 wherein said ion generating unit includes a first ion emitter electrode and a second particle collector electrode and wherein said second particle collector electrode is hollow.

31. The system of claim 25 wherein said ion generating unit includes a first ion emitter electrode and a second particle collector electrode and wherein said second particle collector electrode is a hollow U-shaped electrode.

32. The system of claim 25 wherein said ion generating unit includes a high voltage pulse generator.

33. The system of claim 25 wherein said ion generating unit includes a first wire electrode and a hollow U-shaped electrode.

34. An electro-kinetic air transporter-conditioner system comprising:
an upstanding, elongated housing having an air inlet vent, and an air outlet vent; and

an ion generating unit positioned in said housing, said ion generating unit causing air to flow from the air inlet vent to the outlet vent; and

wherein said ion generating unit includes a first ion emitter electrode and a second particle collector electrode and wherein said second particle collector electrode is a hollow electrodes.

35. The system of claim 34 wherein said electrodes are U-shaped.

36. The system of claim 34 wherein said first electrode is a wire.

37. The system of claim 34 wherein said first electrode is a wire and said second electrode is U-shaped.

38. The system of claim 34 wherein said second collector electrode includes a plurality of elongated fins extending along the elongated housing.

39. The system of claim 34 wherein said ion generating unit includes a high voltage pulse generator.

40. An electro-kinetic air transporter-conditioner system comprising:
an upstanding, elongated housing having an air inlet vent, and an air outlet vent; and

an ion generating unit positioned in said housing, said ion generating unit causing air to flow from the air inlet vent to the outlet vent; and

wherein said ion generating unit includes a first ion emitter electrode and wherein said first ion emitter electrode is wire shaped, and a second particle collector electrode and wherein said second particle collector electrode is a hollow U-shaped electrode;

wherein said first wire shaped ion emitter electrode is located adjacent to the air inlet vent and the second particle collector electrode is located adjacent to the air outlet vent.

41. The system of claim 25 wherein said air inlet vent is covered with horizontal louvers and said front air outlet vent is covered with horizontal louvers.

42. The system of claim 34 wherein said air inlet vent is covered with horizontal louvers and said air outlet vent is covered with horizontal louvers.

43. The system of claim 40 wherein said air inlet vent is covered with horizontal louvers and said air outlet vent is covered with horizontal louvers.

44. The system of claim 40 wherein said second collector electrode has a plurality of elongated fins extending along the elongated housing.

45. The system of claim 34 wherein said second collector electrode includes a plurality of hollow electrodes.

46. The system of claim 34 wherein said second collector electrode includes a plurality of hollow U-shaped electrodes.

47. The system of claim 40 wherein said second collector electrode includes a plurality of hollow U-shaped electrodes.

48. The system of claim 25 wherein said ion generating unit includes a first electrode and a second removable electrode, and said housing has a top and wherein said second removable electrode is removable from said housing through said top.

49. The system of claim 25 including a user control, and wherein said housing has a top portion and said user control is located on said top.

50. The system of claim 48 including a user control located on said top.

51. The system of claim 34 wherein said second particle collector electrode is removable, and said housing has a top and wherein said second particle collector electrode is removable from said housing through said top.

52. The system of claim 34 including a user control, and wherein said housing has a top portion and said user control is located on said top.

53. The system of claim 51 including a user control located on said top.

54. The system of claim 40 wherein said second particle collector electrode is removable, and said housing has a top and wherein said second particle collector electrode is removable from said housing through said top.

55. The system of claim 40 including a user control, and wherein said housing has a top portion and said user control is located on said top.

56. The system of claim 55 including a user control located on said top.

57. The system of claim 25 wherein said ion generating unit includes a pin-ring electrode pair.

58. The system of claim 25 wherein said ion generating unit includes a plurality of pin-ring electrode pairs located one above the other along said upstanding, elongated housing.

59. An electro-kinetic air transporter-conditioner system comprising:
an upstanding, elongated housing having a top; and

an ion generating unit positioned in said housing, said ion generating unit having a first electrode and a second removable electrode, wherein said second removable electrode is removable through said top of said housing.

60. The system of claim 35 including a user control located on said top of said housing.

61. The system of claim 35 including an air inlet vent and an air outlet vent, with the first electrode located adjacent the air inlet vent and the second removable electrode located adjacent the air outlet vent.

62. The system of 35 wherein a user-liftable handle is attached to the second removable electrode and said use-liftable handle extends from the top of said housing.

63. The system of claim 35 wherein said second removable electrode is elongated along a direction of said elongated housing.

64. The system of claim 35 wherein said second removable electrode is elongated and about the same length as said elongated housing.

65. The system of claim 35 wherein said second removable electrode is at least partially removable from the top of said housing for cleaning.

66. An electro-kinetic air transporter-conditioner system comprising:
an upstanding, elongated housing; and
an ion generating unit positioned in said housing, said ion generating unit having a first electrode and a second removable electrode, wherein said second removable electrode is removable from said housing for cleaning.
67. The system of claim 42 including a user control located adjacent to where said second removable electrode is removable from said housing.
68. The system of claim 42 including an air inlet vent and an air outlet vent, with the first electrode located adjacent the air inlet vent and the second removable electrode located adjacent the air outlet vent.
69. The system of 42 wherein a user handle is attached to the second removable electrode and said use handle is for removing said second removable electrode from said housing.
70. The system of claim 42 wherein said second removable electrode is elongated along a direction of said elongated housing.
71. The system of claim 42 wherein said second removable electrode is elongated and about the same length as said elongated housing.

72. The system of claim 42 wherein said second removable electrode is at least partially removable from said housing for cleaning.

73. The system of claim 25 wherein said inlet vent and said outlet vents are elongated along a length of said elongated housing.

74. The system of claim 34 wherein said inlet vent and said outlet vents are elongated along a length of said elongated housing.

75. The system of claim 40 wherein said inlet vent and said outlet vents are elongated along a length of said elongated housing.

76. The system of claim 35 wherein said housing includes an air inlet vent and an air outlet vent and wherein said inlet vent and said outlet vents are elongated along a length of said elongated housing.

77. The system of claim 42 wherein said housing includes an air inlet vent and an air outlet vent and wherein said inlet vent and said outlet vents are elongated along a length of said elongated housing.

78. The system of claim 25 wherein said air inlet vent and said air outlet vents have horizontal louvers.

79. The system of claim 34 wherein said air inlet vent and said air outlet vent have horizontal louvers.

80. The system of claim 40 wherein said air inlet vent and said air outlet vent have horizontal louvers.

81. The system of claim 59 wherein said housing includes an air inlet vent and an air outlet vent, and said air inlet vent and said air outlet vent have horizontal louvers.

82. The system of claim 66 wherein said housing includes an air inlet vent and an air outlet vent, and said air inlet vent and said air outlet vent have horizontal louvers.

83. The system of claim 25 wherein said housing has a cross-section in the shape of a figure eight.

84. The system of claim 34 wherein said housing has a cross-section in the shape of a figure eight.

85. The system of claim 40 wherein said housing has a cross-section in the shape of a figure eight.

86. The system of claim 59 wherein said housing has a cross-section in the shape of a figure eight.
87. The system of claim 66 wherein said housing has a cross-section in the shape of a figure eight.
88. An electro-kinetic air transporter-conditioner system comprising:
an upstanding, elongated housing with a top and an air inlet vent and an air outlet vent;
said air inlet vent is elongate along a direction of elongation of said housing;
said air outlet vent is elongate along the direction of elongation of said housing;
an ion generating unit positioned in said housing, said ion generating unit having a first emitter electrode and a second removable collector electrode;
said second removable collector electrode is elongate along the direction of elongation of said housing and is removable through the top of said housing;
a user-liftable handle secured to the electrodes and located on the top of said housing, said user-liftable handle can lift said second removable collector electrode from said housing; and
a user operated control located on the top of said housing.
89. The system of claim 88 wherein said air inlet vent has a plurality of louvers that are directed across the direction of elongation of said housing; and

said air outlet vent has a plurality of louvers that are directed across the direction of elongation of said housing.

90. The system of claim 88 wherein said second removable collector electrode is hollow.

91. The system of claim 88 wherein said second removable collector electrode is U-shaped.

92. The system of claim 88 wherein said second removable collector electrode is located adjacent to the air outlet vent.

93. The system of claim 88 including a trailing electrode located between said second removable collector electrode and said air outlet vent.

94. The system of claim 88 wherein said housing has a cross-section that is substantially a figure eight.

95. The system of claim 25 including a user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

96. The system of claim 25 including user controls that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

97. The system of claim 95 wherein the pulse mode control can initiate a burst of output ozone.

98. The system of claim 96 wherein the pulse mode control can initiate a burst of output ozone.

99. The system of claim 34 including a user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

100. The system of claim 34 including user controls that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

101. The system of claim 99 wherein the pulse mode control can initiate a burst of output ozone.

102. The system of claim 100 wherein the pulse mode control can initiate a burst of output ozone.

103. The system of claim 40 including a user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

104. The system of claim 40 including user controls that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

105. The system of claim 103 wherein the pulse mode control can initiate a burst of output ozone.

106. The system of claim 104 wherein the pulse mode control can initiate a burst of output ozone.

107. The system of claim 60 including said user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

108. The system of claim 60 including said user control that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

109. The system of claim 107 wherein the pulse mode control can initiate a burst of output ozone.

110. The system of claim 108 wherein the pulse mode control can initiate a burst of output ozone.

111. The system of claim 66 including a user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

112. The system of claim 66 including user controls that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

113. The system of claim 111 wherein the pulse mode control can initiate a burst of output ozone.

114. The system of claim 112 wherein the pulse mode control can initiate a burst of output ozone.

115. The system of claim 88 including said user control that can do at least one of (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

116. The system of claim 88 including said user control that can (1) cause the system to be energized, (2) control a duty cycle of the ion generating unit, (3) control a pulse mode operation.

117. The system of claim 115 wherein the pulse mode control can initiate a burst of output ozone.

118. The system of claim 116 wherein the pulse mode control can initiate a burst of output ozone.

REMARKS

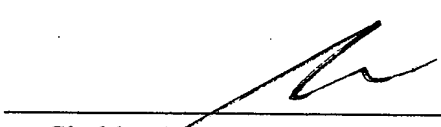

The Commissioner is authorized to charge any underpayment or credit any overpayment to Deposit Account No. 06-1325 for any matter in connection with this response, including any fee for extension of time, which may be required.

Continued examination and allowance is requested.

Respectfully submitted,

Date: December 13, 2001
